

## Implications for a Child when One Partner carries Alpha zero Thalassaemia and the Other carries Delta-beta Thalassaemia

The following information applies only if the partner who carries delta-beta thalassaemia has had a DNA test that shows he or she does not also carry alpha zero thalassaemia.

**There is no particular problem for this couple.** This combination cannot cause an inherited anaemia in their children.

**In each pregnancy**, there are four possibilities.

- The child may not carry any haemoglobin disorder.
- The child may carry alpha zero thalassaemia. This is harmless.
- The child may carry delta-beta thalassaemia. This is harmless.
- The child may inherit alpha zero thalassaemia from one parent and delta-beta thalassaemia from the other. This is harmless.

This couple has the same chance of a healthy family as other couples do.

**When the children grow up**, they should have blood test to see if they have inherited alpha zero or delta-beta thalassaemia. If they have, their partner should have a test "for haemoglobin disorders". It is important to remember this for the future.
